Using a density functional approach based on a Skyrme interaction, thermodynamic properties of finite nuclei are investigated at non-zero temperature. The role of a momentum dependent isovector term is now studied besides volume, symmetry, surface and Coulomb effects. Various features associated with both mechanical and chemical instability and the liquid-gas coexistence curve are sensitive to the Skyrme interaction. The separated effects of the isoscalar term and the isovector term of momentum dependent interaction are studied for a modified SKM($m^* = m$) interaction. The frequently used Skyrme interaction SLy4 is one of the cases considered and is shown to have better features for neutron star studies due to a larger symmetry energy.

I. INTRODUCTION

The study of nuclear properties at finite temperature is important for nuclear astrophysics, medium energy heavy ion collisions and future experiments at the Rare Isotope Beam Facility (RIB). It is also of general interest because of its relation to the study of strongly correlated fermions and to phase transitions in multi-component systems, and in particular to these studies in two component systems. Density functional theory has been extensively used as an approach to such studies in many areas of many body physics. In nuclear physics density functional theory based on a Skyrme interaction approach has been frequently used. Here such an approach will be employed in our study of nuclear properties at finite non-zero temperature. Most applications of density functional theory are for systems at $T = 0$.

The nuclear system has terms that set it apart from other two component binary systems. These include Coulomb terms from the charged proton component, symmetry terms from the nuclear symmetry energy, surface energy terms and momentum dependent terms from a velocity dependence of the nuclear interaction. Questions related to nuclear stability should involve these terms since it is their interplay that determines important features. For example, fission processes are in part an interplay of surface versus Coulomb interactions. The valley of nuclear stability in N and Z involves an interplay of symmetry versus Coulomb interactions. While the Coulomb energy favors systems with large neutron excess in heavy nuclei, symmetry terms favor systems with equal number of protons and neutrons. Nuclei far from the valley of nuclear stability up to neutron drip and proton drip lines are of interest in future RIB experiments. Moreover the Coulomb force is long range and the nuclear force is short range and nearly charge independent. A charge independent nuclear interaction has an associated isospin symmetry. The presence of such terms in the interaction of nucleons make the nuclear case a unique binary system to study. Moreover, realistic nuclei are finite and contain surface terms so that phase transitions in finite systems can be studied. In this paper we incorporate an additional isovector component in the momentum dependence of the interaction, extending our previous studies [1, 2, 3] of properties of heated nuclei. In our previous work we considered an isoscalar momentum dependent term besides volume, surface, non momentum dependent symmetry terms and Coulomb interactions. A momentum dependent isovector term and related isovector effective mass effects are important in a study of properties associated with symmetry terms between protons and neutrons. How various terms in nuclear two component systems manifest themselves at non-zero temperature and how they affect the equation of state, compressibility, chemical and mechanical instability and associated liquid gas coexistence curve are investigated. Without Coulomb terms, the coexistence curve and chemical and mechanical instability curves are symmetric about proton fraction $y = 1/2$. However a stable nucleus such as Pb^{208} at zero temperature has proton fraction $y = 82/208 \approx 80/200 = 0.4$ far from being symmetric in proton number 82 and neutron number 126. When Coulomb terms are included a large asymmetry appears in curves associated with finite temperature properties. The symmetry terms partially restores the symmetry of the curves. We also extend our previous calculation by considering a commonly used Skyrme interaction labeled SLy4 and discuss its properties.

The phase diagram of a one component system is a simple curve of pressure versus density determined by a Maxwell construction. The phase structure in a binary system is considerably more complex than one component systems because of an extra degree of freedom associated with the additional component. The binodal surface is now determined by pressure, temperature and proton fraction. The proton fraction can be different in the denser liquid phase than the less dense gas phase because of the short range of the nuclear symmetry energy. In a nuclear two component system, isospin fractionation [4, 5, 6, 7, 8, 9] is an example where the monomer gas has a large neutron excess. Ref.[9] is a recent reference that contains further references to isospin fractionation. The liquid gas phase

transition was first treated as a one component system [10] and later extended to two components [11] using a Skyrme interaction. Ref.[12] used a relativistic mean field model and studied the role of the symmetry energy on the phase structure in detail. Inclusion of Coulomb and surface terms can be found in Refs.[1, 2, 3] where large asymmetries were shown to appear from the Coulomb term. Pawłowski [13] has also considered the role of the Coulomb term. Some further studies of the nuclear phase transition can be found in Refs.[14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25]. Ref.[23] also includes a discussion of momentum dependent terms, both isoscalar and isovector. Our results will differ somewhat from those of Ref.[23] because we consider a Coulomb term which leads to asymmetries in various quantities in proton fraction. Without a Coulomb interaction symmetry exists around a proton fraction $y = 1/2$ for nuclear stability and for the coexistence loops. The importance of nuclear isospin symmetry in various features of heavy ion collisions can be found in Refs.[7, 26].

In Sect. II, we give the main equations that are necessary for understanding the thermodynamic properties of two component systems with momentum dependent interaction at non-zero temperature. Sect. III is an application of the results of Sect.II to questions associated with the mechanical and chemical instability of hot nuclear matter and the associated liquid-gas phase coexistence curve. A summary and conclusions are given in Sect. IV.

II. THERMODYNAMIC PROPERTIES OF NUCLEI IN A SKYRME DENSITY FUNCTIONAL DESCRIPTION

A. General Results

In this section we present results for the thermodynamic properties of nuclear matter which are extended from the results of Ref.[1, 2, 3] to now include a isovector velocity or momentum dependent interaction. For a Skyrme interaction, this momentum dependent isovector term has some important consequences for both nuclear stability and for phase transition properties.

For a nuclear system of proton (ρ_p) and neutron (ρ_n), this gives the local potential energy density as

$$\begin{aligned} U(\rho_q) = & \frac{t_0}{2} \left(1 + \frac{x_0}{2}\right) \rho^2 - \frac{t_0}{2} \left(\frac{1}{2} + x_0\right) \sum_q \rho_q^2 + \frac{t_3}{12} \left(1 + \frac{x_3}{2}\right) \rho^{\alpha+2} - \frac{t_3}{12} \left(\frac{1}{2} + x_3\right) \rho^\alpha \sum_q \rho_q^2 \\ & + \frac{1}{4} \left[t_1 \left(1 + \frac{x_1}{2}\right) + t_2 \left(1 + \frac{x_2}{2}\right) \right] \rho \tau - \frac{1}{4} \left[t_1 \left(\frac{1}{2} + x_1\right) - t_2 \left(\frac{1}{2} + x_2\right) \right] \sum_q \rho_q \tau_q \\ & + C \rho^\beta \rho_p^2 + C_s \rho^\eta \end{aligned} \quad (1)$$

Here $C \rho^\beta = \frac{4\pi}{5} e^2 R^2$ with $\beta = 0$ and $C_s \rho^\eta = \frac{4\pi R^2 \sigma(\rho)}{\sqrt{V}} = \frac{(4\pi r_0^2 \sigma)}{\sqrt{V^{1/3}}} \rho^{2/3}$ with $\eta = 2/3$ when we approximate the Coulomb and surface effects as coming from a finite uniform sphere of radius $R = r_0 A^{1/3}$ with total charge Z which has the Coulomb energy density of $U_C = \frac{3}{5} \frac{e^2 Z^2}{RV}$ as discussed in Ref.[1]. We have used the value of $R = 6$ fm and $4\pi r_0^2 \sigma = 20.0$ MeV. The values for the force parameters used here are given in Table I. We define an effective mass m_q^* as

$$\begin{aligned} \frac{m}{m_q^*} = & 1 + \frac{2m}{\hbar^2} \left\{ \frac{1}{4} \left[t_1 \left(1 + \frac{x_1}{2}\right) + t_2 \left(1 + \frac{x_2}{2}\right) \right] \rho - \frac{1}{4} \left[t_1 \left(\frac{1}{2} + x_1\right) - t_2 \left(\frac{1}{2} + x_2\right) \right] \rho_q \right\} \\ = & 1 + \frac{2m}{\hbar^2} \left\{ \frac{1}{16} [3t_1 + (5 + 4x_2)t_2] \rho \mp \frac{1}{8} \left[t_1 \left(\frac{1}{2} + x_1\right) - t_2 \left(\frac{1}{2} + x_2\right) \right] \rho(2y - 1) \right\} \end{aligned} \quad (2)$$

where $\rho = \rho_p + \rho_n$ and $y = \rho_p/\rho$. The upper and lower signs are for proton and neutron respectively. When $x_1 = x_2 = -1/2$, the m/m_q^* is a pure isoscalar since the coefficient in the term of ρ_q vanishes. The second form of Eq.(2) shows that the effective masses of neutron and proton are the same for a symmetric nuclear system. We can also see that the neutron effective mass becomes heavier and the proton mass becomes lighter in a neutron rich system while proton effective mass becomes heavier and neutron mass lighter in a proton rich system.

In Table I, the column involving no isovector term is obtained from the column SKM($m^* = m$) by simply setting $x_1 = -1/2$ and $x_2 = -1/2$ and the column with a momentum independent interaction is obtained by setting $t_1 = t_2 = 0$. Both these columns leave the other parameters the same. From the table we see that simply changing these parameters changes various quantities given at the bottom of the table starting with the effective mass and ending with the compressibility. It should be noted that nuclear matter properties for the momentum independent interaction and the SKM($m^* = m$) are the same except for the symmetry energy. Specifically, when two interactions have the same effective mass then the energy and pressure are the same in symmetric systems with the potential energy of the form of Eq.(1) (see Eqs.(42), (45), and (46) of Ref.[3]). And thus the saturation properties will be the

TABLE I: Skyrme parameters are in MeV and fm units. First three columns are from the SKM($m^* = m$) parameter set [1, 27] except $x_0 = -1/6$ and $x_3 = -1/2$. The last column is from the SLy4 parameter set [28]. The nuclear matter properties at the saturation are also shown. The effective mass is for a saturated symmetric nuclear matter.

	SKM($m^* = m$)			SLy4
		No Isovector	Momentum indep.	
t_0	-1089.0	-1089.0	-1089.0	-2488.91
x_0	-1/6	-1/6	-1/6	0.834
t_3	17270	17270	17270	13777.0
x_3	-1/2	-1/2	-1/2	1.354
α	1	1	1	1/6
t_1	251.11	251.11	0	486.82
x_1	0	-1/2	0	-0.344
t_2	-150.66	-150.66	0	-546.39
x_2	0	-1/2	0	-1.000
Effective mass m^*/m	0.999987	0.894430	1	0.694658
Binding energy E_B/A	15.8173	13.3250	15.8176	15.9722
Fermi energy E_F	34.5186	32.0728	34.5188	36.7743
Saturation density ρ_0	0.14509	0.12994	0.14509	0.15954
Symmetry energy S_V	18.6080	23.7451	24.6730	32.0038
Compressibility κ	367.556	312.281	367.562	229.901

same. The only difference between these two columns is then the symmetry energy. By contrast, by simply changing the effective mass, the energy and pressure in the system are changed and thus also the saturation properties. This is seen in Table I by comparing the SKM($m^* = m$) column with the column of no isovector interaction. Our purpose of just varying x_1 and x_2 or t_1 and t_2 without varying other parameters was to isolate the specific role of the isovector and isoscalar terms in SKM($m^* = m$) and thus study their role. We see that various properties of nuclear matter listed in the table are changed and the degree to which they are changed is presented in the results. Changing x_1 and x_2 (or t_1 and t_2) and also changing the other parameters to fit the saturation properties gives rise to yet another Skyrme interaction. Comparisons with many Skyrme interactions can also be made which we hope to do in the future.

For a nuclear system with protons and neutrons with the interaction given by Eq.(1), the non-degenerate Fermi gas limit [1, 2, 3] leads to the following set of equations. The chemical potential has a behavior determined by

$$\begin{aligned}
\mu_q(\rho, y, T) = & T \ln \left[\left(\frac{\lambda_q^3}{\gamma} \right) \rho_q \right] + \frac{T}{2\sqrt{2}} \left(\frac{\lambda_q^3}{\gamma} \right) \rho_q \\
& + \frac{1}{4} \left[t_1 \left(1 + \frac{x_1}{2} \right) + t_2 \left(1 + \frac{x_2}{2} \right) \right] \frac{3}{2} T \sum_q \frac{2m_q^*}{\hbar^2} \left[\rho_q + \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q^2 \right] \\
& - \frac{1}{4} \left[t_1 \left(\frac{1}{2} + x_1 \right) - t_2 \left(\frac{1}{2} + x_2 \right) \right] \frac{3}{2} T \frac{2m_q^*}{\hbar^2} \left[\rho_q + \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q^2 \right] \\
& + t_0 \left(1 + \frac{x_0}{2} \right) \rho + \frac{t_3}{12} \left(1 + \frac{x_3}{2} \right) (\alpha + 2) \rho^{\alpha+1} - \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) \alpha \rho^{\alpha+1} \\
& - t_0 \left(\frac{1}{2} + x_0 \right) \rho_q + \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) (\alpha - 1) 2\rho^\alpha \rho_q - \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) 2\alpha \rho^{\alpha-1} \rho_q^2 \\
& + C\beta \rho^{\beta-1} \rho_p^2 + 2C\rho^\beta \rho_p \delta_{q,p} + \eta C_s \rho^{\eta-1}.
\end{aligned} \tag{3}$$

The equation of state has a form given by

$$\begin{aligned}
P(\rho, y, T) = & \frac{5}{2} T \rho + \frac{5}{2} \frac{T}{2\sqrt{2}} \sum_q \left(\frac{\lambda_q^3}{\gamma} \right) \left(\frac{\rho_q^2}{2} \right) - \frac{3}{2} T \sum_q \frac{m_q^*}{m} \left[\rho_q + \frac{1}{2\sqrt{2}} \left(\frac{\lambda_q^3}{\gamma} \right) \left(\frac{\rho_q^2}{2} \right) \right] \\
& + \frac{t_0}{2} \left(1 + \frac{x_0}{2} \right) \rho^2 + \frac{t_3}{12} \left(1 + \frac{x_3}{2} \right) (\alpha + 1) \rho^{\alpha+2}
\end{aligned}$$

$$\begin{aligned}
& -\frac{t_0}{2} \left(\frac{1}{2} + x_0 \right) \sum_q \rho_q^2 - \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) (\alpha + 1) \rho^\alpha \sum_q \rho_q^2 \\
& + C(\beta + 1) \rho^\beta \rho_p^2 + C_s(\eta - 1) \rho^\eta.
\end{aligned} \tag{4}$$

The energy density is

$$\begin{aligned}
\mathcal{E}(\rho, y, T) = & \frac{3}{2} T \rho + \frac{3}{2} \frac{T}{2\sqrt{2}} \sum_q \left(\frac{\lambda_q^3}{\gamma} \right) \left(\frac{\rho_q^2}{2} \right) \\
& + \frac{t_0}{2} \left(1 + \frac{x_0}{2} \right) \rho^2 - \frac{t_0}{2} \left(\frac{1}{2} + x_0 \right) \sum_q \rho_q^2 + \frac{t_3}{12} \left(1 + \frac{x_3}{2} \right) \rho^{\alpha+2} - \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) \rho^\alpha \sum_q \rho_q^2 \\
& + C \rho^\beta \rho_p^2 + C_s \rho^\eta
\end{aligned} \tag{5}$$

and the entropy is

$$TS(\rho, y, T) = \frac{5}{2} T \rho - T \sum_q \rho_q \ln \left(\frac{\lambda_q^3}{\gamma} \rho_q \right) + \frac{T}{2\sqrt{2}} \sum_q \left(\frac{\lambda_q^3}{\gamma} \right) \left(\frac{\rho_q^2}{4} \right) \tag{6}$$

The effective mass m_q^* and thus λ_q are, in general, isospin dependent [26, 29].

For $m/m_q^* = 1 + a_q \rho = 1 + a\rho + b\rho_q = 1 + \rho(a + b[1 \pm (2y - 1)]/2)$ with $\rho_q = \rho[(1 \mp 1)/2 \pm y]$ and $\lambda_q = \sqrt{2\pi\hbar^2/m_q^*T} = \lambda\sqrt{m/m_q^*}$,

$$a = \frac{m}{2\hbar^2} \left[t_2 \left(1 + \frac{x_2}{2} \right) + t_1 \left(1 + \frac{x_1}{2} \right) \right] \tag{7}$$

$$b = \frac{m}{2\hbar^2} \left[t_2 \left(\frac{1}{2} + x_2 \right) - t_1 \left(\frac{1}{2} + x_1 \right) \right] \tag{8}$$

The $a\rho$ term in the density dependent effective mass comes from the isoscalar term of momentum dependent interaction and the $b\rho_q$ term comes from the isovector term of momentum dependent interaction. Using a and b , we can study the variation of P and μ_q with ρ and y . We can study the behavior of thermodynamic quantities at a fixed P using $dP = 0$ from Eq.(4),

$$\begin{aligned}
dP = & \left\{ \sum_q \left(\frac{5}{2} - \frac{3}{2} \frac{m_q^*}{m} \right) \left[T \rho_q - \frac{T}{2\sqrt{2}} \left(\frac{\lambda_q^3}{\gamma} \right) \left(\frac{\rho_q}{2} \right)^2 \right] \right\} \frac{dT}{T} \\
& + \left\{ \sum_q \left[\left(\frac{5}{2} - \frac{3}{2} \left(\frac{m_q^*}{m} \right)^2 \right) T \rho_q + \left(\frac{35}{8} - \frac{15}{4} \left(\frac{m_q^*}{m} \right) + \frac{3}{8} \left(\frac{m_q^*}{m} \right)^2 \right) \frac{T}{2\sqrt{2}} \left(\frac{\lambda_q^3}{\gamma} \right) (\rho_q^2) \right] \right. \\
& + \left[t_0 \left(1 + \frac{x_0}{2} \right) \rho^2 + \frac{t_3}{12} \left(1 + \frac{x_3}{2} \right) (\alpha + 1) (\alpha + 2) \rho^{\alpha+2} \right. \\
& - t_0 \left(\frac{1}{2} + x_0 \right) \left(\sum_q \rho_q^2 \right) - \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) (\alpha + 1) (\alpha + 2) \rho^\alpha \left(\sum_q \rho_q^2 \right) \\
& \left. \left. + C(\beta + 1)(\beta + 2) \rho^\beta \rho_p^2 + C_s(\eta - 1) \eta \rho^\eta \right] \right\} \frac{d\rho}{\rho} \\
& - \left\{ \left[t_0 \left(\frac{1}{2} + x_0 \right) + \left(\frac{\alpha + 1}{6} \right) t_3 \left(\frac{1}{2} + x_3 \right) \rho^\alpha - (\beta + 1) C \rho^\beta \right] \rho \rho_3 - (\beta + 1) C \rho^\beta \rho^2 \right. \\
& + \sum_q \left[\frac{3}{2} T \rho \left(\pm \frac{m_q^*}{m} \right) \left(1 - b \rho_q \left(\frac{m_q^*}{m} \right) \right) \right. \\
& \left. \left. \mp \frac{T}{2\sqrt{2}} \left(\frac{\lambda_q^3}{\gamma} \right) \rho \rho_q \left(\left(\frac{5}{2} - \frac{3}{2} \frac{m_q^*}{m} \right) + b \rho_q \left(\frac{m_q^*}{m} \right) \frac{3}{4} \left(\frac{5}{2} - \frac{1}{2} \frac{m_q^*}{m} \right) \right) \right] \right\} dy \tag{9}
\end{aligned}$$

This equation gives the condition determining $y_m(\rho)$ where both $\partial P/\partial y = 0$ and $\partial \rho/\partial y = 0$,

$$0 = \left[t_0 \left(\frac{1}{2} + x_0 \right) + \left(\frac{\alpha + 1}{6} \right) t_3 \left(\frac{1}{2} + x_3 \right) \rho^\alpha - (\beta + 1) C \rho^\beta \right] \rho \rho_3 - (\beta + 1) C \rho^\beta \rho^2$$

$$\begin{aligned}
& + \sum_q \left[\frac{3}{2} T \rho \left(\pm \frac{m_q^*}{m} \right) \left(1 - b \rho_q \left(\frac{m_q^*}{m} \right) \right) \right. \\
& \quad \left. \mp \frac{T}{2\sqrt{2}} \left(\frac{\lambda_q^3}{\gamma} \right) \rho \rho_q \left(\left(\frac{5}{2} - \frac{3}{2} \frac{m_q^*}{m} \right) + b \rho_q \left(\frac{m_q^*}{m} \right) \frac{3}{4} \left(\frac{5}{2} - \frac{1}{2} \frac{m_q^*}{m} \right) \right) \right]
\end{aligned} \tag{10}$$

The $y_m(\rho)$ is the value of y with lowest pressure P for a given density ρ and temperature T and is independent of ρ for a momentum independent Skyrme interaction with $x_3 = -1/2$ and $\beta = 0$ as considered in Ref.[1, 2]. The x_3 term and the density dependent effective mass for a momentum dependent Skyrme force introduce a small ρ -dependence in y_m . The isovector momentum dependent term (x_1 and x_2 terms) introduce large ρ -dependence in y_m as we will see later. The $y_m(\rho)$ curve cross the coexistence loop at the equal concentration point y_E where the liquid and gas phases have the same y value.

From Eq.(3),

$$\begin{aligned}
d\mu_q = & \left\{ \ln \left[\left(\frac{\lambda_q^3}{\gamma} \right) \rho_q \right] - \frac{3}{2} - \frac{1}{2} \frac{1}{2\sqrt{2}} \left(\frac{\lambda_q^3}{\gamma} \right) \rho_q \right. \\
& + \frac{1}{4} \left[t_1 \left(1 + \frac{x_1}{2} \right) + t_2 \left(1 + \frac{x_2}{2} \right) \right] \frac{3}{2} \sum_q \frac{2m_q^*}{\hbar^2} \left[\rho_q - \frac{1}{2} \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q^2 \right] \\
& - \frac{1}{4} \left[t_1 \left(\frac{1}{2} + x_1 \right) - t_2 \left(\frac{1}{2} + x_2 \right) \right] \frac{3}{2} \frac{2m_q^*}{\hbar^2} \left[\rho_q - \frac{1}{2} \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q^2 \right] \Big\} dT \\
& + \left\{ \left[\frac{T}{\rho} + \frac{T}{2\sqrt{2}} \frac{\rho_q}{\rho} \left(\frac{\lambda_q^3}{\gamma} \right) \right] \left(\frac{5}{2} - \frac{3}{2} \frac{m_q^*}{m} \right) \right. \\
& + \frac{1}{4} \left[t_1 \left(1 + \frac{x_1}{2} \right) + t_2 \left(1 + \frac{x_2}{2} \right) \right] \frac{3}{2} T \sum_q \frac{2m_q^*}{\hbar^2} \frac{\rho_q}{\rho} \left[\frac{m_q^*}{m} + \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q \left(\frac{5}{2} - \frac{1}{2} \frac{m_q^*}{m} \right) \right] \\
& - \frac{1}{4} \left[t_1 \left(\frac{1}{2} + x_1 \right) - t_2 \left(\frac{1}{2} + x_2 \right) \right] \frac{3}{2} T \frac{2m_q^*}{\hbar^2} \frac{\rho_q}{\rho} \left[\frac{m_q^*}{m} + \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q \left(\frac{5}{2} - \frac{1}{2} \frac{m_q^*}{m} \right) \right] \\
& + \left[t_0 \left(1 + \frac{x_0}{2} \right) + \frac{t_3}{12} \left(1 + \frac{x_3}{2} \right) (\alpha + 2)(\alpha + 1) \rho^\alpha - \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) \alpha(\alpha + 1) \rho^\alpha \right. \\
& - t_0 \left(\frac{1}{2} + x_0 \right) \frac{\rho_q}{\rho} + \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) 2(\alpha - 1)(\alpha + 1) \rho^{\alpha-1} \rho_q - \frac{t_3}{12} \left(\frac{1}{2} + x_3 \right) 2\alpha(\alpha + 1) \rho^{\alpha-2} \rho_q^2 \\
& \left. + C\beta(\beta + 1) \rho^{\beta-2} \rho_p^2 + 2C(\beta + 1) \rho^{\beta-1} \rho_p \delta_{q,p} + C_s \eta(\eta - 1) \rho^{\eta-2} \right] \Big\} d\rho \\
& + \left\{ \pm \left[T \frac{\rho}{\rho_q} + \frac{T}{2\sqrt{2}} \rho \left(\frac{\lambda_q^3}{\gamma} \right) \right] \left(1 + \frac{3}{2} b \rho_q \frac{m_q^*}{m} \right) \right. \\
& + \frac{1}{4} \left[t_1 \left(1 + \frac{x_1}{2} \right) + t_2 \left(1 + \frac{x_2}{2} \right) \right] \frac{3}{2} T \sum_q (\pm) \frac{2m_q^*}{\hbar^2} \rho \left[\left(1 - b \rho_q \left(\frac{m_q^*}{m} \right) \right) + \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q \left(2 + b \rho_q \frac{1}{2} \frac{m_q^*}{m} \right) \right] \\
& \mp \frac{1}{4} \left[t_1 \left(\frac{1}{2} + x_1 \right) - t_2 \left(\frac{1}{2} + x_2 \right) \right] \frac{3}{2} T \frac{2m_q^*}{\hbar^2} \rho \left[\left(1 - b \rho_q \left(\frac{m_q^*}{m} \right) \right) + \frac{\lambda_q^3}{2^{5/2}\gamma} \rho_q \left(2 + b \rho_q \frac{1}{2} \frac{m_q^*}{m} \right) \right] \\

\end{aligned} \tag{11}$$

This equation determines the various curves of $\partial\mu_q/\partial\rho = 0$, $\partial\mu_q/\partial y = 0$, chemical instability curve, etc.

FIG. 1: Equation of state $P(\rho)$ for fixed $y = 0, 0.2, y_m(\rho)$ (the proton concentration with minimum pressure defined by Eq.(10)) for thick lines from top to bottom and $y = 0.5, 0.8, 1.0$ for thin lines from bottom to top. The solid line is for the modified SKM($m^* = m$) interaction with both isoscalar and isovector momentum dependent terms, the dash-dotted line is for a momentum dependent but isovector independent term, and the dashed line is for momentum independent terms only. The lowest thin dashed curve overlaps here with the lowest thin solid curve which have $y = 0.5$.

III. APPLICATIONS TO NUCLEAR MECHANICAL AND CHEMICAL INSTABILITY AND THE LIQUID-GAS PHASE TRANSITION

A. Equation of State with Isoscalar and Isovector Momentum Dependent Terms

The equation of states ($P(\rho)$ curve) for various proton fraction y at a fixed temperature of $T = 10$ MeV are shown in Fig.1. The solid lines are $P(\rho)$ for momentum dependent interaction (modified SKM($m^* = m$)) with both isoscalar and isovector terms. The dash-dotted lines are for a momentum dependent Skyrme interaction with isoscalar term only and the dashed lines are for a Skyrme interaction without momentum dependent terms which are the same cases considered in Ref.[3]. For various values of pressure P at $T = 10$ MeV, the curve of $y(\rho)$, $\mu_q(y)$, and $\mu_q(\rho)$

are shown in Fig.2, Fig.3, and Fig.4 respectively. The basic behaviors of the curves are the same independent of which force parameters are used. For example, the $y(\rho)$ and $\mu_q(\rho)$ curves of Figs.2 and 4 for low pressure P exhibit a closed loop separated from a vertical line at low density for all three cases. Since the overall behaviors which are independent of force parameters are studied in previous papers [1, 2, 3], the discussions below are concentrated more on the differences between different force parameters.

The pressure for a given density ρ and y increases from the corresponding value for the case of a momentum independent Skyrme interaction (dashed curve) by the momentum dependent isoscalar term (dash-dotted curve) and decreases much more by the isovector term (solid curve). In Fig.1, the crossing of curves for different y values appears explicitly for $y = 0.2$ and 0.5 with a momentum dependent isovector term (solid lines). This crossing is related to the ρ dependence of y_m , the proton concentration with minimum pressure defined by Eq.(10), which comes from the momentum dependent terms and the three body isovector term.

For $y = 0$ and with an isovector momentum dependent term the $P(\rho)$ curve has a spinodal instability region in the density range of about $1/5 < \rho/\rho_0 < 1/3$ of nuclear saturation density ρ_0 and around $P = 0.08$ ($0.0755 \sim 0.0834$) MeV/fm³. In Figs.2 and 4 the curves for $P = 0.08$ MeV/fm³ show a gap in the range of $0.0401 < \rho < 0.0598$ fm⁻³ due to the spinodal behavior for $y = 0$. From solid curves of Fig.1 we can see the horizontal cut of $P = 0.08$ MeV/fm³ gives negative value of y in this density range. This spinodal instability of $P(\rho)$ curve for $y = 0$ causes the cut of coexistence curve by the $y = 0$ line which can be seen in Figs.5 and 6.

For $y = 1/2$ the $P(\rho)$ curve for momentum dependent interaction with both isoscalar and isovector terms (solid curve) overlaps with the curve for momentum independent interaction (dashed curve). The SKM($m^* = m$) interaction used here (Table I), with both isoscalar and isovector momentum dependent terms, has the effective mass of $m_q^* = m$ for $y = 1/2$ which is the same value with the momentum independent interaction case. The $y(\rho)$ curves at fixed P in Fig.2 show that the curves for a momentum independent force (dashed line) are tangent to the curves for fully momentum dependent force (solid line) at $y = 1/2$. Similarly the $\mu_q(y)$ curves in Fig.3 show that the dashed curve crosses the corresponding solid curve at $y = 1/2$. In Fig.4 this crossing appears at the point with large ρ which corresponds to $y = 1/2$. Since $m^* = m$ at $y = 1/2$ for a full momentum dependent force the $P(\rho)$ curve at $y = y_m(\rho)$ is closer to the curve for momentum independent force than to the curve for a momentum dependent interaction without an isovector term.

Figs.2 and 6 each show that the momentum dependent isovector term introduces a large ρ dependence in the y_m of Eq.(10), the proton concentration y having minimum pressure for a given density ρ . The $y_m(\rho)$ is independent of the density ρ for a momentum independent Skyrme force. The isoscalar momentum dependent term introduces a small increase of y_m with increasing ρ while the isovector momentum dependent term introduces a large decrease of y_m with increasing ρ .

Figs.1 - 6 show that the basic behavior of various curves remains qualitatively the same for the various cases considered here. However the isoscalar momentum dependent term and the isovector momentum dependent term move in an opposite direction for the various curves compared to the curves of a momentum independent case. The isovector term has a larger effect than an isoscalar term.

The $y(\rho)$ curve shown in Fig.2 is the horizontal cut of a fixed P in Fig.1. Fig.2 shows the closed loops of $y(\rho)$ for low pressure P is reduced to a much smaller loop by the isoscalar momentum dependent term (dash-dotted line) from the momentum independent interaction (dashed line). The isovector momentum dependent term makes the loop much larger. Thus, the full momentum dependent interaction (solid line) enlarges the loop from the momentum independent loop. For higher P which has no closed loop, the isoscalar momentum dependent term makes the density ρ for a given y and P smaller than ρ for momentum independent force and the isovector momentum dependent term makes ρ larger. The full momentum dependent term makes ρ for a given y and P larger than the ρ for momentum independent force. The proton fraction y for a given ρ and P is farther away from y_m for full momentum dependent interaction than other interactions due to the smaller value of symmetry energy. The solid curve for $P = 0.08$ MeV/fm³ shows a cut off of the curve by $y = 0$ line for the density range of $0.04 \sim 0.06$ fm⁻³.

Fig.3 and 4 show that the chemical potential has a somewhat complicated relative effect arising from momentum dependent terms. Except in the regions with medium y in Fig.3 or larger value of ρ in Fig.4, the isoscalar momentum dependent term makes the chemical potential higher while isovector momentum dependent term makes it lower. The closed loop for low P in Fig.4 is reduced to a much smaller size by momentum dependent isoscalar term (dash-dotted curve) from a loop for a momentum independent interaction (dashed curve) while it is enlarged by momentum dependent isovector term (solid curve). The low μ_q portion of the curves for higher P in Fig.4, which corresponds to the region with lower y value, shows the density for a given μ_q becoming much smaller by the isoscalar momentum dependent term from the value for the momentum independent case while it becomes much larger by the isovector momentum dependent term. The horizontal straight thick solid line (the full momentum dependent SKM($m^* = m$) force) at low μ_p for $P = 0.08$ MeV/fm³ in Fig.4 represents the cut due to the condition of $y \geq 0$ for the density range of $0.04 < \rho < 0.06$ fm⁻³.

FIG. 2: The $y(\rho)$ dependence for fixed pressure of $P = 0, 0.015, 0.05, 0.08, 0.2, 0.3, 0.4, 0.5 \text{ MeV}\cdot\text{fm}^{-3}$. The curves are the same as in Fig.1. The thin horizontal lines are for $y_m(\rho)$ curve define by Eq.(10).

B. Liquid-Gas Phase Transition and the Coexistence Curve and Instability

For a one component system the coexistence curve is a line obtained by the familiar Maxwell construction as already noted. For a two component system the coexistence region is a surface obtained as follows. The condition for coexistence between the two phases requires the proton chemical potentials to be the same in two phases and, similarly, the neutron chemical potentials must be the same in the two phases at a given pressure and temperature. Note that the proton fraction or neutron fraction need not be the same in each of the two phases. The two phases have the same proton fraction at the line of equal concentration y_E which is the line of intersection between the coexistence surface and the surface of y_m satisfying Eq.(10). In fact, the liquid phase should be a more symmetric system than the gas phase because of the symmetry potential as seen in Refs.[1, 2]. This observation goes under the name of isospin fractionation.

Figs.5 and 6 show features of the coexistence curves. Also shown in Fig.6 are the mechanical and chemical instability

FIG. 3: Chemical potential μ_p (thick lines) and μ_n (thin lines) as a function of y for $P = 0.015, 0.05, 0.08, 0.2$, and 0.5 . The curves are the same as in Fig.1

loops and curves of $\partial\mu_q/\partial\rho = 0$. In Figs.5 and 6 the small kink at lowest y side of the coexistence loop for the interaction with an isovector momentum dependent term might have come from a numerical problem. For SLy4 (curve with + sign in Fig.5), there is a small island of coexistence near the y_E region. It is not clear if this is a numerical problem or a physical feature. Further detailed studies are required.

Fig.5 shows that the coexistence loops in the neutron rich side (smaller y side) are smaller than the loops in the proton rich side for three cases of SKM($m^* = m$) parameter sets. For the SLy4 parameter set, the coexistence loop at the neutron rich side is larger than the loop at the proton rich side. Ref.[2] shows that the Coulomb interaction moves y_E to a smaller proton fraction y and makes the coexistence loops smaller in the neutron rich side than in the proton rich side. The SKM($m^* = m$) parameter sets used in Ref.[2] has no isovector three body term ($x_3 = -1/2$) while SLy4 parameter sets has a negative three body isovector term.

In Fig.6 we can see the instability curves are inside of the coexistence loop for all three force parameter sets. The mechanical instability loops are inside of the chemical instability loops and tangent to each other at the point of y_m lines (the horizontal line in this figure). The chemical instability loops are inside of the coexistence loops and tangent

FIG. 4: Same as Fig.3 but as a function of ρ . The straight horizontal portion of the thick solid curve (momentum dependent force with both isoscalar and isovector terms) for $P = 0.08 \text{ MeV/fm}^3$ at low μ_p just represents the cut in the density range of $0.04 < \rho < 0.06 \text{ fm}^{-3}$ due to the condition of $y \geq 0$.

to each other at the critical point, i.e., the point with highest pressure on the coexistence curve.

In Figs.5 and 6, the loops for the isovector momentum dependent case (solid line) has a cut at $y = 0$ which is related with the spinodal behavior of $P(\rho)$ curve for $y = 0$ in Fig.1. The smaller symmetry energy allows the system to be more asymmetric and thus to reach the boundary of $y = 0$ or $y = 1$. The SKM($m^* = m$) force with both isoscalar and isovector momentum dependent terms has the smallest symmetry energy while the SLy4 force has the largest symmetry energy among forces used here (see Table I). Fig.5 shows the coexistence loops for SLy4 are more symmetric than the loops for SKM($m^* = m$) parameter sets and the full SKM($m^* = m$) force has the most asymmetric coexistence loops. The cut of coexistence loop by $y = 0$ indicates that the SKM($m^* = m$) force with both isoscalar and isovector terms has too small of a symmetry energy for a description of nuclear system even though we have used $x_0 = -1/6$ instead of $x_0 = 0.5$ to have a larger symmetry energy.

The pressure of the coexistence curve on the neutron rich side for a given value of y (Fig.5) becomes higher due to the momentum dependent isoscalar term (dash-dotted line) than the pressure for momentum independent interaction

FIG. 5: $P(y)$ plot for coexistence curve. The curves are the same as in Fig.1. The curve with + sign is for SLy4 parameter.

(dashed line) and also moves the peak to higher y . By contrast the momentum dependent isovector term (solid line) makes the pressure lower and moves the peak to lower y . The effects of isoscalar and isovector term work in opposite direction for the coexistence curve on the proton rich side compare to the effects for neutron rich side. For SLy4 the system without an isovector or isoscalar momentum dependent term does not saturate at the usual normal density region. However, the isovector momentum dependent term in SLy4 has the same sign as the isoscalar momentum dependent term thus both isoscalar and isovector terms would make the pressure of the coexistence curve of neutron rich side higher than momentum independent case. This might also make the coexistence loop in neutron rich side larger than the loop in proton rich side. In Fig.6 the loops for the momentum dependent isoscalar case (dash-dotted line) is smallest and thus mostly inside among the loops while the loops for the momentum dependent isovector case (solid line) are largest and thus mostly outside. The loops for the momentum independent case (dashed line) are tangent to the loops for the momentum dependent case with both isoscalar and isovector terms (solid line) at $y = 1/2$ where $m^* = m$ for both cases. The curves of $\partial\mu_q/\partial\rho = 0$ (thin curves in Fig.6) also show that the isovector momentum dependent term has an opposite and larger effect than the isoscalar momentum dependent term.

FIG. 6: The closed loops are for coexistence curves, chemical instability boundary curves, and mechanical instability curves from outmost loops to inside loops at $T = 10$ MeV. Also shown by thin lines are $\partial\mu_q/\partial\rho = 0$ for proton (opened downward) and for neutron (opened upward). The horizontal lines are the $y_m(\rho)$ determine by Eq.(10).

IV. SUMMARY AND CONCLUSIONS

A density functional theory based on a Skyrme nuclear interaction is used to study the temperature dependent properties of a two component system of strongly interacting protons and neutrons. The paper extends our previous studies by including an isovector momentum dependent interaction. As before, Coulomb and finite size surface effects are also contained in the description of various properties. The nuclear interaction has a velocity or momentum dependent term and in a medium this momentum dependence can be discussed as an effective mass to lowest order in it. The momentum dependence has both isoscalar and isovector terms. Our prior study in Ref.[3] suppressed the isovector part by using a particular choice of Skyrme parameters. This greatly simplified the original calculations of the stability and coexistence properties. Here we now explore the mechanical and chemical instability of a two component system and also the coexistence features associated with a liquid gas phase transition incorporating an isovector

momentum dependence besides other terms mentioned above. While qualitative results have a similar behavior with and without a momentum dependence (isoscalar and isovector), significant quantitative differences exist. Moreover, we extended our calculations to include the frequently used Skyrme interaction called SLy4 [28].

Each term, Coulomb, volume, surface, symmetry, effective mass or momentum dependence, both isoscalar and isovector, play a unique role in determining the finite temperature stability properties and coexistence features as shown in various figures in this paper. For example, the Coulomb interaction leads to a pronounced asymmetry in the coexistence loops shown in Fig.5. Moreover the equal concentration point y_E , where the liquid and gas have the same proton fraction, moves away from $y_E = 1/2$ without Coulomb forces to a point where the proton fraction is close to the valley of stability when Coulomb forces are included. For example $y_E = 0.410$ for a momentum independent force, 0.414 for a isoscalar momentum dependent force, 0.379 for a isovector momentum dependent force, and 0.402 for SLy4. The y_E with Coulomb included is somewhat insensitive to the nuclear force. However, the pressure at y_E is more sensitive. Specifically, $P = 0.0138$ MeV/fm³ for momentum independent case, 0.0236 for isoscalar case, 0.0127 for isovector case, and 0.0262 for SLy4.

A model with no Coulomb terms would have identical loops in y around the point of intersection $y_E = 1/2$ of equal concentration. The SLy4 interaction has the interesting property of making the left coexistence loop of lower proton fraction more pronounced than the right loop of high proton fraction. This particular feature in the height of the right versus left loop is not observed with the other SKM($m^* = m$) interaction discussed in this paper. In particular, the right loop is still more pronounced or higher than the left loop for SKM($m^* = m$). For SKM($m^* = m$), the isoscalar momentum dependent term raises the pressure of the coexistence loop on the neutron rich side while the isovector momentum dependent term, which has an opposite sign from the isoscalar term, lowers the pressure. For SLy4, both the isoscalar and isovector terms have the same sign and thus would raise the pressure of the coexistence loop on the neutron rich side. The SLy4 has also a non zero effect from an isovector three body term which was zero for SKM($m^* = m$). Besides this feature the SLy4 loop at higher y side is narrower in y for a given T and P than the SKM($m^* = m$) loops. From this observation we can conclude that the coexistence and stability behaviors are sensitive to the choice of Skyrme interaction parameters. The SLy4 has a higher symmetry energy than the other interactions used in this paper as shown in Table I. Moreover a higher left loop means that the liquid and gas phases can coexist at higher pressures at a given temperature with a more neutron rich gas and a lesser rich neutron liquid, i.e., $y_G < y_L < y_E < 1/2$ for the left loop. A narrowing of the coexistence loop brings the y_G and y_L closer together thereby reducing the proton fraction difference in the gas and liquid phases.

The momentum dependent isovector term in SKM($m^* = m$) force has an opposite and larger effect than the momentum dependent isoscalar term. A momentum dependent isovector term makes the symmetry energy smaller and thus the coexistence loops and the mechanical and chemical instability loops become more asymmetric. The small value of symmetry energy for full momentum dependent interaction makes the y value for a given ρ and P farther away from y_m . The pressure for a given ρ and y at fixed T becomes larger by the isoscalar momentum dependent term while it becomes smaller by the isovector momentum dependent term.

Symmetry energy terms arising from momentum independent and momentum dependent terms tend to restore the symmetry of the loops. The coexistence loops and instability loops for SKM($m^* = m$) with both isoscalar and isovector momentum dependent terms have the smallest symmetry energy. Therefore they are the furthest away from y_E for this force and thus have a cut due to the $y \geq 0$ condition. This feature presents a problem for using an interaction with too small of a symmetry term in neutron star studies. The coexistence loops for SLy4, which has the largest symmetry energy, are closer to its y_E than for the SKM($m^* = m$) parameter sets. This suggests that the large symmetry energy terms of the SLy4 are very important in restoring the isospin symmetry in the system and also better in neutron star studies.
